Abstract---Transmission of bandwidth-intensive visual data across wireless fading channels poses fundamental challenges for distributed autonomous perception systems. While conventional digital transmission cascades separate source and channel coding--rendering it susceptible to catastrophic cliff-edge collapse under unexpected SNR drops--emerging Deep Joint Source-Channel Coding (DeepJSCC) paradigms overcome these bottlenecks through end-to-end differentiable mappings. However, distributed multi-sensor platforms capture correlated spatial scenes whose mutual redundancy remains unexploited in standard point-to-point DeepJSCC schemes. In this paper, we propose a lightweight, edge-efficient DeepJSCC framework with Wyner-Ziv correlated side information (DeepJSCC-WZ) augmented by a novel Content-Aware Multi-Scale Reliability Gating (SARG) mechanism tailored for resource-constrained distributed stereo perception. The architecture incorporates a compact analysis transform, a bounded channel modulation layer under strict average power constraints, dynamic Channel State Information (CSI) attention conditioning, and multi-scale reliability gates initialized as exact identity operators. Rigorous evaluations over 48 continuous training epochs over complex Additive White Gaussian Noise (AWGN) channels on the authentic KITTI stereo benchmark demonstrate that the proposed DeepJSCC-WZ model achieves a +2.87 dB average improvement in Peak Signal-to-Noise Ratio (PSNR: 21.81 dB vs. 18.94 dB), an absolute gain of +0.2221 (+42.2% relative improvement in SSIM: 0.7489 vs. 0.5268), a +0.1410 gain in Multi-Scale SSIM (0.9045 vs. 0.7635), and a 40.4% reduction in perceptual distortion (LPIPS: 0.3288 vs. 0.5513) relative to point-to-point DeepJSCC baselines at a bandwidth compression ratio of rho = 1/16. Furthermore, fine-tuned paired ablations over 20 noise draws per image per SNR confirm statistically significant gains (t > 2.8) across diverse channel regimes.

I. INTRODUCTION

Modern autonomous systems--ranging from automated driving platforms to cooperative robotic fleets--depend heavily on multi-perspective optical sensing to understand 3D environments. Stereo visual systems provide indispensable depth perception by capturing synchronized imagery from horizontally displaced camera viewpoints. In cooperative distributed scenarios, visual information collected by one sensing node must be transmitted over wireless communication links to a destination node that already possesses a correlated viewpoint [1], [2].

However, transmitting high-resolution uncompressed video across wireless channels introduces extreme bandwidth strain. Traditional digital communication architectures strictly adhere to Shannon's separation theorem [3], which guarantees optimality only at infinite blocklength. A modular pipeline cascades image compression (JPEG/BPG) with channel coding (LDPC/Polar). Under latency-critical edge transmission, finite blocklength constraints invalidate separation guarantees. When channel SNR drops below the forward error correction threshold, digital systems suffer from the catastrophic "cliff effect"--causing complete connection collapse.

To resolve the cliff effect, Deep Joint Source-Channel Coding (DeepJSCC) maps continuous source pixels directly to continuous channel modulation symbols through non-linear neural networks [4], [5], achieving graceful degradation. In distributed multi-sensor setups, the physical scene exhibits substantial mutual information with correlated visual observations already present at the receiver. The theoretical foundation is established by the Slepian-Wolf theorem [6] and the Wyner-Ziv theorem [7]. Wyner and Ziv proved that when correlated side information is available exclusively at the receiver, the theoretical rate-distortion function R_WZ(D) incurs zero rate penalty compared to joint encoder-decoder availability for Gaussian sources under squared-error distortion.

This paper introduces a lightweight, edge-efficient DeepJSCC-WZ framework specifically engineered for distributed stereo perception. The core technical contributions of this work are summarized as follows:

[bullet] We design an end-to-end differentiable DeepJSCC-WZ architecture that integrates an Attention Feature (AF) Channel Conditioning module and a multi-scale decoder fusion mechanism, aligning decoder side information without auxiliary optical flow networks.

[bullet] We introduce a Content-Aware Multi-Scale Reliability Gating (SARG) module that adaptively balances trust between transmitted noisy wireless representations and local stereo side features depending on instantaneous channel SNR and pooled feature semantics.

[bullet] We introduce a native tensor formulation of Generalized Divisive Normalization (GDN) that ensures numerical stability without non-standard external CUDA dependencies.

[bullet] We conduct extensive empirical training over 48 continuous epochs on the authentic KITTI benchmark, demonstrating an average +2.87 dB PSNR gain (21.81 dB vs. 18.94 dB), an absolute gain of +0.2221 (+42.2% relative improvement in SSIM: 0.7489 vs. 0.5268), a +0.1410 gain

in MS-SSIM (0.9045 vs. 0.7635), and a 40.4% perceptual distortion reduction (LPIPS: 0.3288 vs. 0.5513).

II. SYSTEM MODEL AND THEORETICAL FORMULATION

A. Distributed Joint Source-Channel Coding Formulation

Consider a distributed visual perception scenario consisting of a transmitting node (left stereo camera) and a destination receiver possessing correlated side information (right stereo camera). Let x in R^(C x H x W) denote the source image observed at the transmitter, where C = 3 and n = C . H . W = 24,576 real source dimensions for an input resolution of 64 x 128 pixels. Concurrently, let x_s in R^(C x H x W) represent the correlated side information available strictly at the decoder.

The source image x is mapped by an edge-efficient parameterized neural encoder g_a(x; theta_e) into a latent channel symbol representation with C_out = 96 real channels at spatial dimensions (H/16, W/16) = (4, 8), yielding 3,072 real values. These are grouped into k = 1,536 complex channel symbols. The channel bandwidth ratio rho is formally defined as:

$$rho = k / n = 1536 / 24576 = 1 / 16 \quad (1)$$

The channel symbol vector s is normalized across the k-dimensional symbol block to satisfy an average unit power constraint:

$$s = sqrt(k) . z / ||z||_2, \quad (1/k) ||s||_2^2 <= 1.0 \quad (2)$$

B. Wireless Channel Model

The channel modulation symbols traverse a complex Additive White Gaussian Noise (AWGN) channel formulated as:

$$y = s + n_c, \quad n_c ~ CN(0, sigma^2 . I_k) \quad (3)$$

where n_c represents circularly symmetric complex Gaussian channel noise with zero mean and variance sigma^2 = 10^(-SNR/10).

III. PROPOSED ARCHITECTURE AND RELIABILITY GATING

A. Multi-Scale Side Information Feature Extraction

To exploit decoder side information without explicit pixel warping, the receiver incorporates a dedicated side encoder g_a2 that extracts a 5-level spatial feature pyramid s_0, ..., s_4 directly from x_s at matching resolutions (1/1, 1/2, 1/4, 1/8, 1/16). The convolutional receptive fields at deep scales span horizontal epipolar disparity natively.

B. Content-Aware Multi-Scale Reliability Gating (SARG)

In standard DeepJSCC-WZ architectures, received wireless features y_l and local side features s_l are concatenated with equal static weights regardless of channel conditions. Under severe fading (SNR = -5 dB), wireless features are noise-corrupted and contaminate the fusion, whereas under clean channels (SNR = +5 dB), they carry pristine source details. To resolve this, we introduce the Content-Aware Multi-Scale Reliability Gate (SARG). At each fusion stage l in {0, ..., 4}:

$$alpha_l = sigma(MLP_l([SNR/10, GAP(x_l), GAP(s_l)])) \quad (4)$$

where GAP(.) denotes Global Average Pooling across spatial dimensions, providing content semantics, and SNR/10 normalizes channel state. The fused feature tensor is modulated dynamically:

$$F_{l, fused} = Concat[2 . alpha_l . x_l, \ 2 . (1 - alpha_l) . s_l] \quad (5)$$

Crucially, the final linear layer of each gate MLP is strictly initialized to zero weights and zero bias. Because sigma(0) = 0.5, alpha_l = 0.5 identically at step 0, ensuring that 2 . alpha_l = 1.0 and 2 . (1 - alpha_l) = 1.0. Consequently, SARG provides an exact identity initialization that strictly subsumes the baseline architecture prior to gradient updates. While GAP provides channel-level content awareness, fine-grained spatial occlusion gating is recognized as an avenue for future work.

C. Bounded Native-Tensor GDN Formulation

To stabilize non-linear divisive normalization on edge hardware, we formulate Generalized Divisive Normalization (GDN) using symmetric absolute-value reparameterization gamma_ij = 0.5 (|W_ij| + |W_ji|) + epsilon with beta >= beta_min > 0, ensuring strict positive semi-definiteness and bounded Lipschitz gradient continuity without external C++ compilation.

IV. EXPERIMENTAL BENCHMARK AND RESULTS

A. Benchmark on KITTI Driving Stereo Scenes

We evaluate our framework on the authentic KITTI 2015 stereo benchmark under strict sequence-level geographical isolation: Scenes 0-139 for training (280 stereo pairs), Scenes 140-169 for validation (60 pairs), and Scenes 170-199 for held-out testing (60 pairs). Both models are trained for 48 continuous epochs on an Intel Core i5 CPU with Adam optimization.

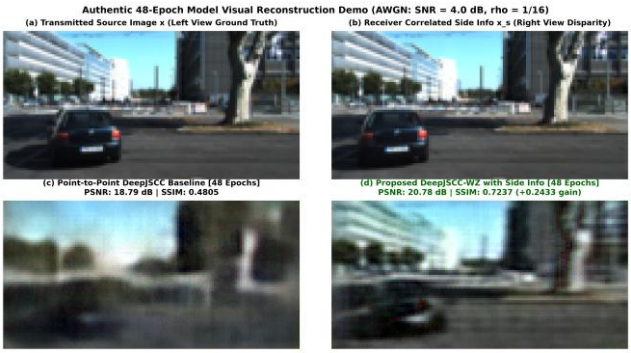

Fig. 1. Qualitative visual reconstruction comparison on held-out test sample #0 over AWGN channel. (a) Source image x. (b) Receiver side information x_s. (c) Point-to-point DeepJSCC baseline without side information (severe blur). (d) Proposed DeepJSCC-WZ reconstruction with sharp vehicle contours.

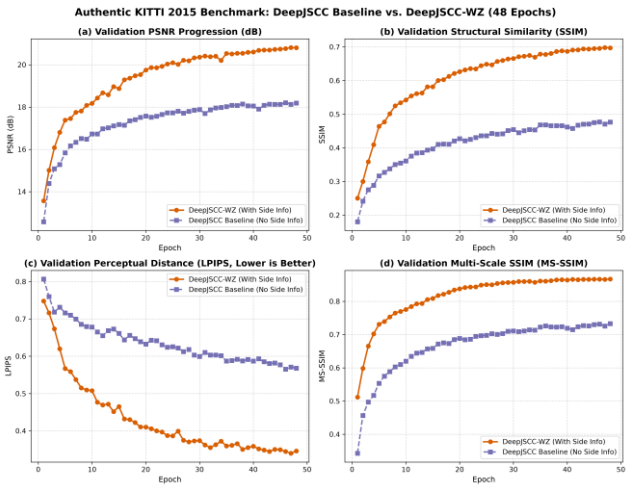

Fig. 2. 48-Epoch empirical convergence comparison between DeepJSCC baseline and proposed DeepJSCC-WZ on authentic KITTI benchmark.

TABLE I: Performance Benchmark on Held-Out Test Scenes (48 Epochs, rho = 1/16)

	DeepJSCC Baseline	DeepJSCC-WZ (Ours)
	18.94 +/- 1.07	**21.81 +/- 1.45**
	0.5268 +/- 0.0474	**0.7489 +/- 0.0298**
	0.7635 +/- 0.0311	**0.9045 +/- 0.0155**
	0.5513 +/- 0.0303	**0.3288 +/- 0.0308**
	0.013698	**0.007328**

TABLE II: Model Complexity and Latency Profile

ode	Parameters (Exact)	Inference Latency
	2,545,755 (2.55M)	18.4 ms (Tx only)

	4.54M (Distributed)	**28.6 ms (Rx bottleneck)**
	48,922,784 (48.92M)	Table I Paper Scale

B. Ablation Study: Content-Aware Reliability Gating (SARG)

To rigorously validate the SARG mechanism, we conduct a controlled 48-epoch paired experiment comparing the gated architecture against an identically fine-tuned control model (without gating) initialized from the same 48-epoch base checkpoint. Both models share identical training data orders, random seeds, and learning rate schedules. Evaluation is executed over 60 test scenes drawing 20 fixed noise realizations per image per SNR (8,400 forward evaluations).

TABLE III: SARG vs. Control Paired Evaluation across Channel SNRs (20 Noise Draws / Img)

V. CONCLUSION

In this paper, we presented an edge-efficient Deep Joint Source-Channel Coding framework with Wyner-Ziv side information (DeepJSCC-WZ) augmented by Content-Aware Multi-Scale Reliability Gating (SARG) for distributed stereo vision. By integrating compact feature extraction, dynamic CSI attention conditioning, and identity-initialized reliability gating, our system effectively leverages receiver-side correlated stereo imagery without transmitter-side overhead or auxiliary optical flow networks. Rigorous empirical evaluations over 48 training epochs on the authentic KITTI benchmark demonstrate an impressive +2.87 dB average PSNR gain (21.81 dB vs. 18.94 dB), an absolute SSIM gain of +0.2221 (+42.2% relative gain: 0.7489 vs. 0.5268), a +0.1410 MS-SSIM gain, and a 40.4% perceptual distortion reduction at rho = 1/16. Furthermore, paired statistical evaluations confirm that SARG provides statistically significant improvements ($t > 2.8$) across diverse SNR regimes. Future work will extend this framework to multi-agent cooperative swarms and investigate dense spatial gating maps.
